punctuation.py

--> The if statement was only occuring when the character WAS a punctuation, not when it wasnt.

optimize.py

--> When concattenating the rest of the DNA guess onto the attempt, the coder forgot to keep the guess in the string.

--> What ended up happening was that the attempt would just turn into whatever the string was from current position to the end of the starting string

evaluate.py

--> You forgot to do the last evaluation. Because of how the loop worked, the loop would end before the last number was

--> calculated into total.
